Modern Techniques in Modelling

#### Outline for session 1

- What are ordinary differential equations (ODEs)?
- How do we use ODEs to model an epidemic?
- Using the R package deSolve
  - Practical: SI, SIR, SEIR models in R

#### Reminder: Difference equations

In the previous session, we explored difference equations:

$$S(t+1) = S(t) - \beta S(t) I(t) + \beta S(t) I(t) + \beta S(t) I(t) - \gamma I(t)$$

$$R(t+1) = R(t) + \gamma I(t)$$

$$= current \\ value + change \\ in value$$

These changes are the interesting part – they are what define the behaviour of the system.

#### **Difference equations**

$$S(t+1) = S(t) - \beta S(t) I(t)$$

$$I(t+1) = I(t) + \beta S(t) I(t) - \gamma I(t)$$

$$R(t+1) = R(t) + \gamma I(t)$$

**Ordinary differential equations** have a similar structure, but only the rate of change is given:

$$dS(t)/dt = -\beta S(t) I(t)$$
  

$$dI(t)/dt = \beta S(t) I(t) - \gamma I(t)$$
  

$$dR(t)/dt = \gamma I(t)$$

The explicit dependence on time is often omitted (e.g. S is written instead of S(t))

#### **Difference equations**

$$S(t+1) = S(t) - \beta S(t) I(t)$$

$$I(t+1) = I(t) + \beta S(t) I(t) - \gamma I(t)$$

$$R(t+1) = R(t) + \gamma I(t)$$

**Ordinary differential equations** have a similar structure, but only the rate of change is given:

$$dS/dt = -\beta S I$$
  

$$dI/dt = \beta S I - \gamma I$$
  

$$dR/dt = \gamma I$$

The explicit dependence on time is often omitted (e.g. S is written instead of S(t))

Mathematically, dX/dt represents the derivative of X with respect to time (i.e. the rate at which X is changing over time).

For example, is S is the number of susceptibles, t is measured in days, and we have

$$dS/dt = -\beta SI = -2$$

then this means the number of susceptibles is currently shrinking at a rate of 2 people per day, and in one day's time will have around\* 2 people fewer.

\* not exactly 2, because over the course of that day, the value of  $-\beta$  S I will change!

We will look at examples in the next section.

## How do we model an infectious disease outbreak using ODEs?

#### With variables:

*S* the number of susceptible people

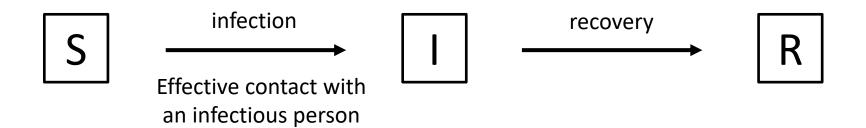

*I* the number of infectious people

*R* the number of recovered people

$$N = S + I + R$$
 the total number of people

Let's look at the "infection" and "recovery" transitions in more detail.

Rate of effective contact with an infectious person:

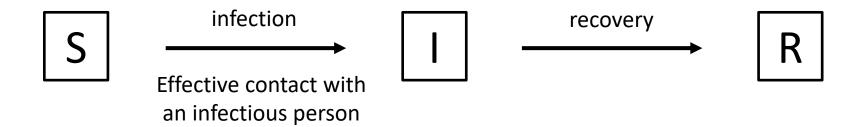

A person contacts *c* people per day...

A fraction I/(S+I+R) = I/N of these contacts are infectious...

A fraction p of these contacts with infectious people are effective...

$$rate(S \rightarrow I) =$$

Rate of effective contact with an infectious person:

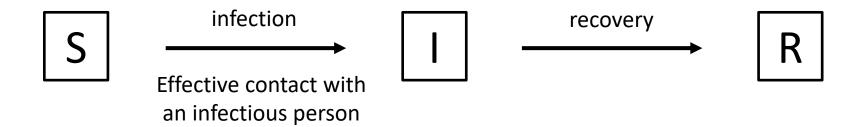

A person contacts *c* people per day...

A fraction I/(S+I+R) = I/N of these contacts are infectious...

A fraction p of these contacts with infectious people are effective...

$$rate(S \to I) = c \times I/N \times p \times S$$

Rate of effective contact with an infectious person:

A person contacts *c* people per day...

A fraction I/(S+I+R)=I/N of these contacts are infectious...

A fraction p of these contacts with infectious people are effective...

$$rate(S \to I) = \beta \times I/N \times S \qquad (\beta = cp)$$

$$\begin{array}{c|c}
S & \xrightarrow{\beta I/N S} & & & \\
\hline
 & & \\

Rate of recovery:

Suppose we know the infectious period lasts for d days...

Then the rate of recovery is 1/d per day...

(e.g. if something happens 2x per day, on average it happens every 0.5 days)

$$rate(I \to R) = \gamma \times I \qquad (\gamma = 1/d)$$

$$\begin{array}{c|c}
S & \xrightarrow{\beta I/N S} & \hline
\end{array}$$

Rate of recovery:

Suppose we know the infectious period lasts for d days...

Then the rate of recovery is 1/d per day...

(e.g. if something happens 2x per day, on average it happens every 0.5 days)

$$rate(I \to R) = \gamma \times I \qquad (\gamma = 1/d)$$

$$\begin{array}{c|c}
S & \xrightarrow{\beta I/N S} & \boxed{I} & \xrightarrow{\gamma I} & \boxed{R}
\end{array}$$

Note that above, both transitions are specified as:

"rate per person per day" times "number of people at risk"

infection:  $\beta I/N$  times S

recovery:  $\gamma$  times I

Often in model diagrams, the "number of people at risk" term is omitted, and implied by where the arrow is coming from.

$$\begin{array}{c|c}
S & \xrightarrow{\beta I/N} & \boxed{I} & \xrightarrow{\gamma} & \boxed{R}
\end{array}$$

Note that above, both transitions are specified as:

"rate per person per day" times "number of people at risk"

infection:  $\beta I/N$  times S

recovery:  $\gamma$  times I

Often in model diagrams, the "number of people at risk" term is omitted, and implied by where the arrow is coming from.

$$\begin{array}{c|c}
S & \xrightarrow{\beta I/N} & & & \\
\hline
\text{Infection} & & & \\
\hline
\end{array}$$

To turn this into ODEs, we include each rate twice: once negative for the "leaving" (subtracting from) compartment, and once positive for the "entering" (adding to) compartment.

$$dS/dt = -(\beta I/N)S$$

$$dI/dt = (\beta I/N)S - \gamma I$$

$$dR/dt = \gamma I$$

$$\begin{array}{c|c}
S & \xrightarrow{\beta I/N} & \boxed{I} & \xrightarrow{\gamma} & \boxed{R}
\end{array}$$

A full ODE model specification has the following elements:

System of ordinary differential equations

$$dS/dt = -(\beta I/N)S$$

$$dI/dt = (\beta I/N)S - \gamma I$$

$$dR/dt = \gamma I$$

$$N = S + I + R$$

Initial conditions

**Parameters** 

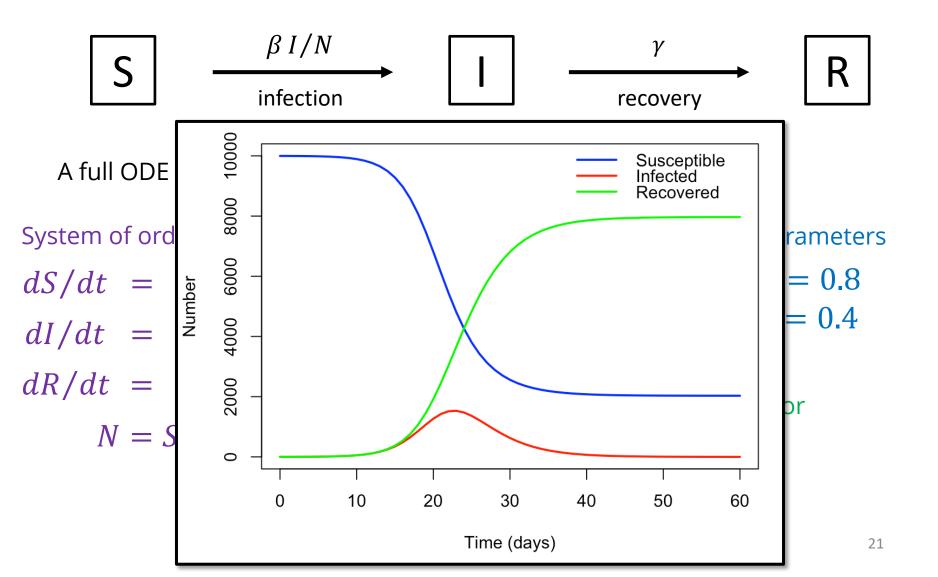

$$S(0) = 9,999$$
  $\beta = 0.8$ 

$$I(0) = 1$$
  $\gamma = 0.4$   $R(0) = 0$ 

Times to solve system for

$$t \in \{0, 1, 2, \dots, 60\}$$

# Solving ODE models in R with the desolve package

#### Using the R package desolve

- R package which can numerically solve ODEs
- Provides the function ode () to solve your model
- You provide to ode ():
  - y, initial conditions
  - times, time points to solve the system for
  - parms, parameters
  - func, the system of ODEs as an R function
  - (optionally, others we will discuss later...)
- ode () returns a matrix with numerical solutions to the ODEs and the times

#### Susceptible Infected (SI) model

Individuals are either susceptible or infected:

$$S \xrightarrow{\beta I/N} I$$

Susceptible individuals become infected via transmission rate  $\beta$ .

$$dS/dt = -(\beta I/N)S$$
$$dI/dt = (\beta I/N)S$$

- Provide to ode():
  - y, initial conditions

Assume we have population of N = 100, with 1 infected individual:

$$N < -100$$
 $I_0 < -1$ 
 $S_0 < -N - I_0$ 
 $Y < -c(S = S_0, I = I_0)$ 

- Provide to ode():
  - times, time points to solve the system for

Let's solve the equation over a period of 50 days, which we will write inside a vector as follows:

```
times <- seq(from = 0, to = 50, by = 1)
# or times <- 0:50
```

- Provide to ode():
  - parms, parameters

We have just one parameter, the transmission rate:

```
parms \leftarrow c (beta = 0.4)
```

```
- Provide to ode():

    func, the system of ODEs as an R function

  SI model <- function(times, state, parms)</pre>
     # Get variables
     S <- state["S"]
     I <- state["I"]</pre>
     N < - S + T
     # Get parameters
     beta <- parms["beta"]</pre>
     # Define differential equations
     dS \leftarrow -(beta * I / N) * S
     dI \leftarrow (beta * I / N) * S
     res <- list(c(dS, dI))
     return (res)
```

```
# Solve equations
output raw <- ode(y = y, times = times,
                 func = SI model, parms = parms)
# Convert matrix to data frame for easier manipulation
output <- as.data.frame(output raw)</pre>
head (output)
        ## time

## Practical 1 Solving ODEs using deSolve

#### Practical 1

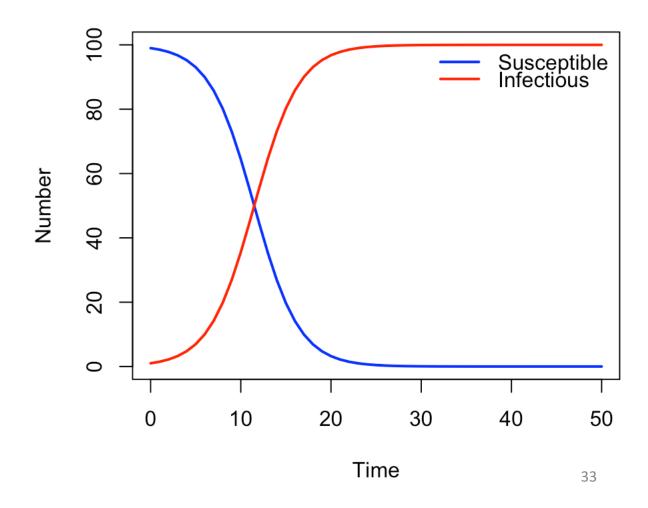

- Objective: Solve SI, SIR, SEIR models using deSolve
- Answer questions 1, 2 and 3
- Question 4, adding vaccination, is optional.

Note: If you are stuck with a grid of plots in R, use par(mfrow = c(1,1)) to go back to single-plot mode.

#### Practical 1: SI model

1a. Increase the initial number of infectious individuals. What happens to the output?

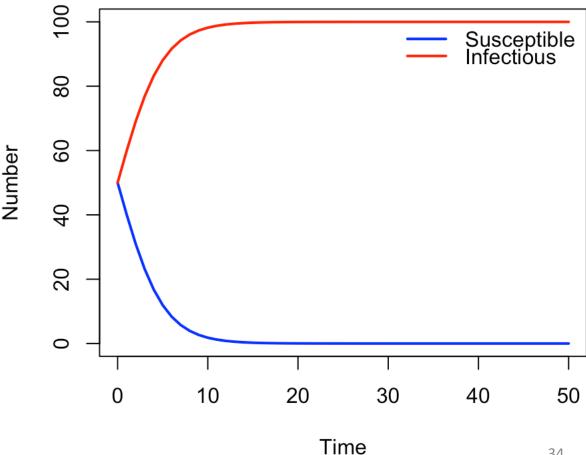

#### Practical 1: SI model

1a. Increase the initial number of infectious individuals. What happens to the output?

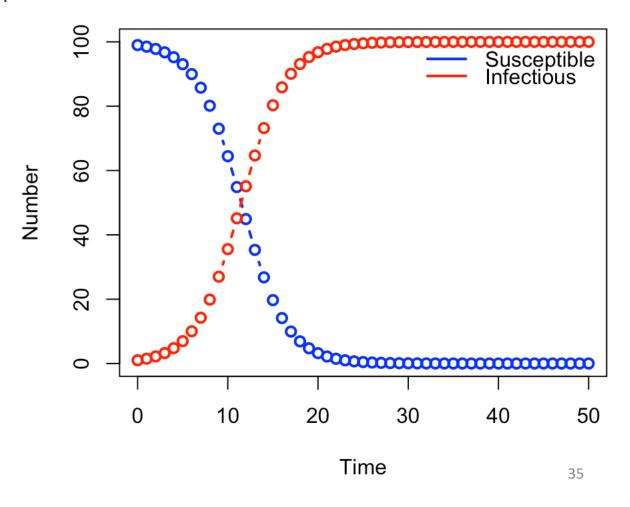

The number of infectious has a higher starting point, but the same growth rate from that level, and the same endpoint.

#### Practical 1: SI model

1c. Increase the value of the by argument (in the times vector). What happens to the output?

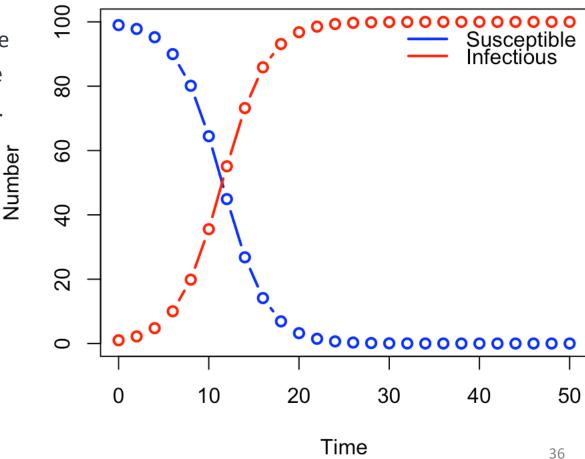

#### Practical 1: SI model

1c. Increase the value of the by argument (in the times vector). What happens to the output?

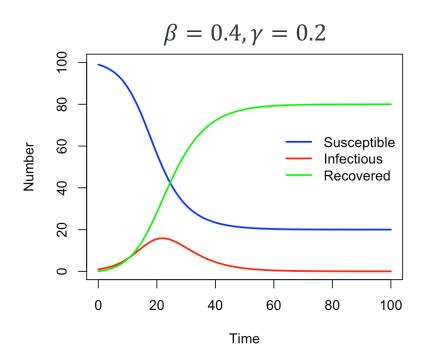

The solution points become more spaced out, but trace the same underlying curve.

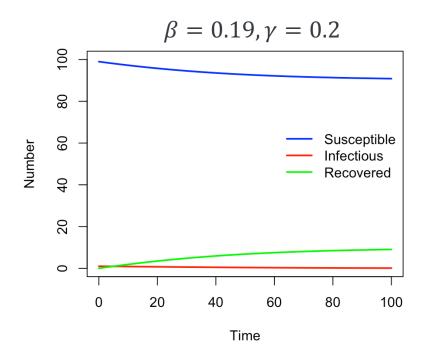

#### Practical 1: SIR model

2b. Change the value of the transmission rate so that the basic reproduction number is less than one, i.e.  $R_0 < 1$ . What happens to the output?

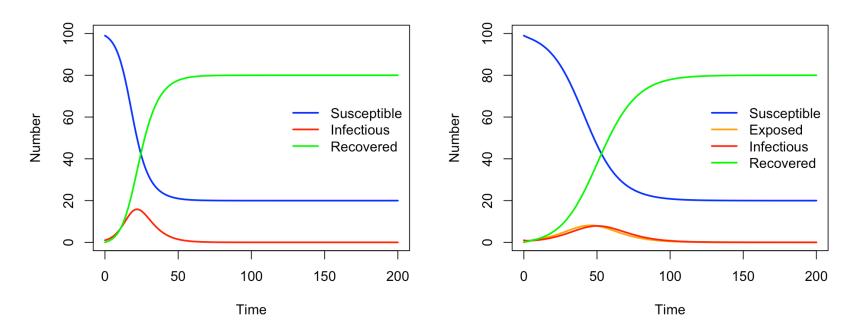

Recall that for an SIR model, the basic reproduction number  $R_0=\beta/\gamma$ . When  $R_0<1$ , the epidemic does not take off.

#### Practical 1: SEIR model

3b. How does the model output differ from the SIR model you coded previously?

Approximately the same number of people get infected, but the epidemic takes approximately twice as long; generation interval is twice as long.

See Wallinga and Lipsitch 2007, especially section 3a, for discussion of the generation interval, the growth rate and the reproduction number in epidemic models.

#### ODEs session 1 summary

- ODE models are specified in terms of state variables and their rates of change
- We have seen how to construct ODE systems starting from a flowchart-style model diagram
- To solve an ODE model, we need to provide initial conditions for the state variables, parameter values, and times over which to solve the model
- We have learned how to use deSolve to solve ODEs in R
- Next session: Advanced use of deSolve.

# Ordinary Differential Equations, session 2

Modern Techniques in Modelling

#### Outline for session 2

- Recap on ODEs
- How does numerical integration work?
- Advanced use of deSolve
  - Practical: time-varying parameters, events, and Rcpp

# Ordinary differential equations: Recap

**Parameters** 

$$\begin{array}{c|c}
S & \xrightarrow{\beta I/N} & & & \\
\hline
\text{Infection} & & & \\
\hline
\end{array}$$

A full ODE model specification has the following elements:

System of ordinary differential equations

$$dS/dt = -(\beta I/N)S$$

$$dI/dt = (\beta I/N)S - \gamma I$$

$$dR/dt = \gamma I$$

$$N = S + I + R$$

**Initial conditions** 

$$S(0) = 9,999$$
  $\beta = 0.8$   
 $I(0) = 1$   $\gamma = 0.4$   
 $R(0) = 0$ 

Times to solve system for

$$t \in \{0, 1, 2, \dots, 60\}$$

Starting from the initial conditions, we use **numerical integration** (e.g. with deSolve) to evaluate the variables at times *t*.

# How does numerical integration of ODEs work?

# Numerical integration

Systems of ODEs define curves which usually don't have analytical solutions.

We use **numerical integration** to approximate these curves.

Usually done using piecewise polynomials.

Recall – examples of polynomials

linear y = ax + b

quadratic  $y = ax^2 + bx + c$ 

cubic  $y = ax^3 + bx^2 + cx + d$ 

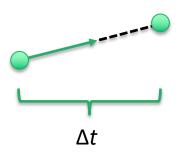

Simplest example: piecewise linear approximation (Euler's method)

#### Euler's method

#### Choose a time step, $\Delta t$ .

- 1. Start at initial point y(0), i.e. t = 0.
- 2. Use ODEs to get "slope" of function at this point (d**y** / dt).
- 3. Move forward to  $t' = t + \Delta t$  along a straight line with this "slope".
- 4. Repeat steps 2 3.

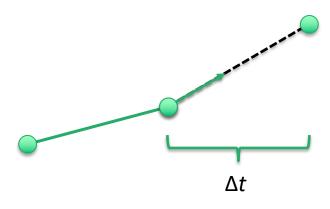

#### Euler's method

#### Choose a time step, $\Delta t$ .

- 1. Start at initial point y(0), i.e. t = 0.
- 2. Use ODEs to get "slope" of function at this point (d**y** / dt).
- 3. Move forward to  $t' = t + \Delta t$  along a straight line with this "slope".
- 4. Repeat steps 2 3.

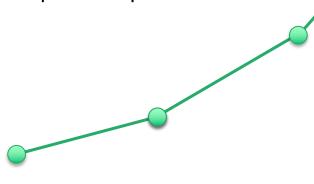

#### Euler's method

Choose a time step,  $\Delta t$ .

- 1. Start at initial point y(0), i.e. t = 0.
- 2. Use ODEs to get "slope" of function at this point (d**y** / dt).
- 3. Move forward to  $t' = t + \Delta t$  along a straight line with this "slope".
- 4. Repeat steps 2 3.

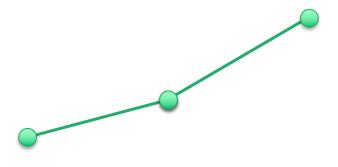

Note: This is very much like pretending your ODEs are difference equations!

Instead of a piecewise linear function, we can use a piecewise quadratic function.

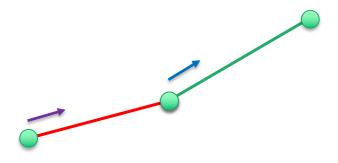

Instead of a piecewise linear function, we can use a piecewise quadratic function.

Note that for piece 1, we have a slope measurement on the left side and a slope measurement on the right side.

Instead of a piecewise linear function, we can use a piecewise quadratic function.

Note that for piece 1, we have a slope measurement on the left side and a slope measurement on the right side.

We can use these two slopes to construct a quadratic piece instead of a linear piece.

Instead of a piecewise linear function, we can use a piecewise quadratic function.

Note that for piece 1, we have a slope measurement on the left side and a slope measurement on the right side.

We can use these two slopes to construct a quadratic piece instead of a linear piece.

And so on...

Instead of a piecewise linear function, we can use a piecewise quadratic function.

Note that for piece 1, we have a slope measurement on the left side and a slope measurement on the right side.

We can use these two slopes to construct a quadratic piece

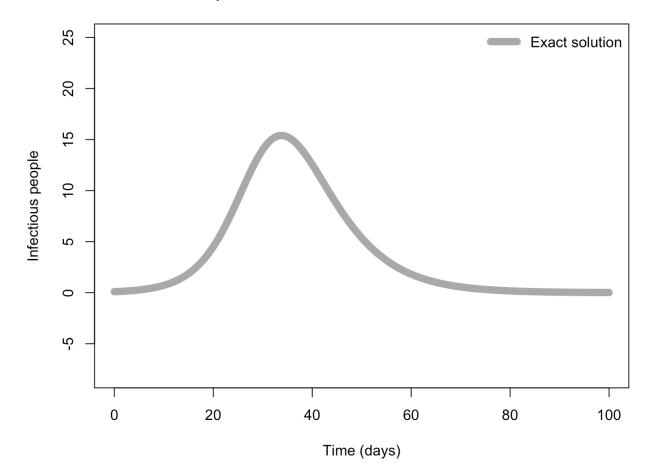

instead of a linear piece.

And so on...

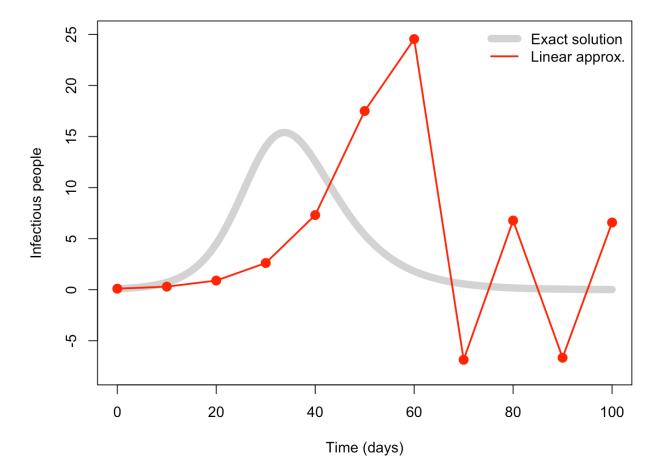

In general, the higher degree polynomials we use, the better our approximation, at a cost of increased computation.

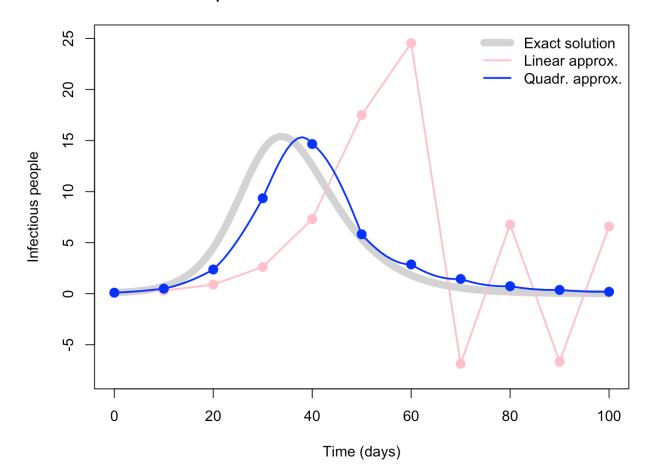

In general, the higher degree polynomials we use, the better our approximation, at a cost of increased computation.

#### Usage in deSolve

In deSolve, we can specify what approximation method we want to use with the method argument to ode():

#### Usage in deSolve

In deSolve, we can specify what approximation method we want to use with the method argument to ode():

#### Usage in desolve

#### Some common methods:

"euler" Euler's method

"rk4" 4th-order Runge-Kutta

"lsoda" Petzold & Hindmarsh

Don't use this!

Commonly used, quite good

Robust (and the default);

automatic step size

# Advanced use of deSolve

# Advanced use of deSolve package

Time-dependent changes to parameters Events, with or without a "trigger" Speeding up your model with Rcpp

#### Time dependent parameters

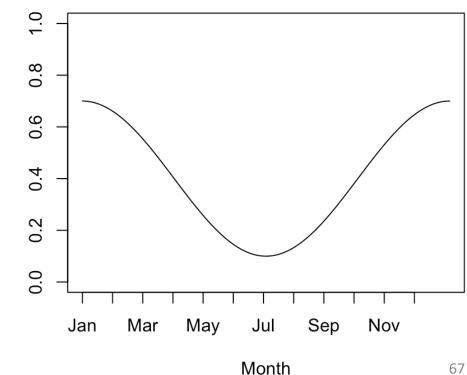

Parameters, like the transmission rate, are "inputs" into the model.

We have been treating these as constants, but they can also vary with time.

What are some reasons the transmission rate might vary over time?

Seasonality...

We have been treating these as constants, but they can also vary with time.

What are some reasons the transmission rate might vary over time?

Behaviour change...

#### **Events**

With ODEs, changes that happen to state variables are fundamentally "smooth" – there are no sudden jumps.

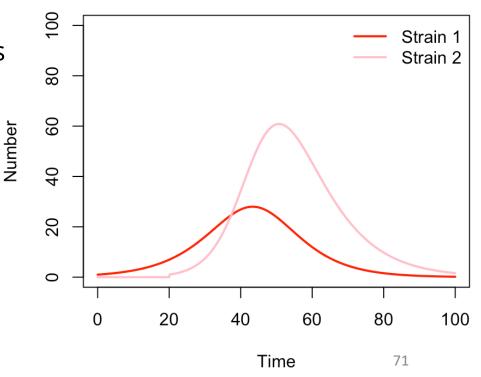

#### Events

With ODEs, changes that happen to state variables are fundamentally "smooth" – there are no sudden jumps.

What if we need to change the state variables at an instant?

e.g. a new strain of the virus gets introduced on November 20...

#### Time dependent parameters

Time-dependent parameters can be brought directly into the ODE function.

```
SI model <- function(t, state, parms) {</pre>
  # Get variables
  S <- state["S"]
  I <- state["I"]</pre>
  N \leftarrow S + I
  # Get parameters
  beta <- parms["beta"]</pre>
  # Define differential equations
  dS \leftarrow -(beta * S * I) / N
  dI \leftarrow (beta * S * I) / N
  res <- list(c(dS, dI))
  return (res)
```

#### Time dependent parameters

Time-dependent parameters can be brought directly into the ODE function.

```
SI seasonal model <- function(t, state, parms) {
  # Get variables
  S <- state["S"]
  I <- state["I"]</pre>
  N \leftarrow S + I
  # Get parameters
  beta max <- parms["beta max"]</pre>
  period <- parms["period"]</pre>
  beta \leftarrow beta max / 2 * (1 + \sin(2*pi*t / period))
  # Define differential equations
  dS \leftarrow -(beta * S * I) / N
  dI \leftarrow (beta * S * I) / N
  res <- list(c(dS, dI))
  return (res)
```

- deSolve has the capability to include 'events'
- This can be used when you want to change the value of a state variable based on some condition
- Events can be specified as a data.frame, or in a function.
- Events can also be triggered by a root function.
  - use a data.frame to specify times at which events occur
  - use root function to trigger an event based on some condition

- -Let's look at an example of using a root function
- We want to predict infection in a livestock population
  - managed births, i.e. birth rate is a function of some target farm size K
  - assume that death occurs at longer time scale than infection, so we don't include it

$$\frac{dS}{dt} = bN(K - N)/K - \beta SI/N$$

$$\frac{dI}{dt} = \beta SI/N$$

where N = S + I.

We have our model function,

```
SI open model <- function(times, state, parms) {
  ## Define variables
  S <- state["S"]
  I <- state["I"]</pre>
  N < - S + T
  # Extract parameters
  beta <- parms["beta"]</pre>
  K <- parms["K"]</pre>
  b <- parms["b"]
  # Define differential equations
  dS \leftarrow b * N * (K - N) / K - (beta * S * I) / N
  dI \leftarrow (beta * S * I) / N
  res <- list(c(dS, dI))
  return (res)
```

- Our event is going to be a herd cull, removing a fraction  $\tau$ .
- Firstly, we need to write a function which changes the appropriate state variables

```
event I cull <- function(times, state, parms) {</pre>
  ## Define variables
  I <- state["I"]</pre>
  # Extract parameters
  tau <- parms["tau"]
  I <- I * (1 - tau) # cull the infected
population
  state["I"] <- I
  return (state)
```

Secondly, we need to write a function which triggers the event

```
root <- function(times, state, parms) {</pre>
  ## Define variables
  S <- state["S"]
  I <- state["I"]</pre>
  N \leftarrow S + I
  # Extract parameters
  K <- parms["K"]</pre>
  # Our condition is if more than half of the
target herd size becomes infected
  condition \leftarrow !(I > K * 0.5) # This is a logical
condition (TRUE/FALSE)
  return(as.numeric(condition)) # Make this
numeric, event occurs if root==0
```

What does the output look like?

## Using Rcpp

- Rcpp is an R package that provides an interface between R and C++
- -The func input in ode can be written in C++
- Overcomes some of R's speed issues

#### Using Rcpp

```
#include <Rcpp.h>
using namespace Rcpp;
// [[Rcpp::export]]
List SIR cpp model (Numeric Vector t, Numeric Vector state,
                   NumericVector parms)
{
    // Get variables
    double S = state["S"];
    double I = state["I"];
    double R = state["R"];
    double N = S + I + R;
    // Get parameters
    double beta = parms["beta"];
    double gamma = parms["gamma"];
    // Define differential equations
    double dS = -(beta * S * I) / N;
    double dI = (beta * S * I) / N - gamma * I;
    double dR = gamma * I;
    NumericVector res vec = NumericVector::create(dS, dI, dR);
    List res = List::create(res vec);
    return (res);
```

# Practical part 2

# Practical part 2

- Objective: implement SIR with time dependent transmission and use the events function in deSolve
- Answer parts I, II
- Part III is optional
